

Theme 1: Abstract Reasoning

Lecture 3: Inductive Correctness Proofs

Matthieu Sozeau

Inria & Paris Diderot University, Paris 7

October 2014

Example: The Append function

- Type:

$$\text{Append} : \text{List}[\star] \times \text{List}[\star] \rightarrow \text{List}[\star]$$

- Specification:

$$\begin{aligned} \text{Spec_Append}(\ell_1, \ell_2, \ell) = & \\ & |\ell| = |\ell_1| + |\ell_2| \wedge \\ & \forall i \in \text{Nat}. (0 \leq i < |\ell_1|) \Rightarrow \ell[i] = \ell_1[i] \wedge \\ & \forall i \in \text{Nat}. (0 \leq i < |\ell_2|) \Rightarrow \ell[|\ell_1| + i] = \ell_2[i] \end{aligned}$$

- Implementation:

$$\begin{aligned} [] @ \ell &= \ell \\ (a \cdot \ell_1) @ \ell_2 &= a \cdot (\ell_1 @ \ell_2) \end{aligned}$$

- Correctness:

$$\forall \ell_1, \ell_2, \ell. (\ell_1 @ \ell_2 = \ell) \Rightarrow \text{Spec_Append}(\ell_1, \ell_2, \ell)$$

Implementation vs. Specification

- Assume we want to define

$$f : \text{Dom} \rightarrow \text{CoDom}$$

- Consider an abstract specification

$$\text{Spec}_f(\text{In}, \text{Out}) \subseteq \text{Dom} \times \text{CoDom}$$

- Let Impl_f be an implementation of f (e.g., as a recursive function)
- The implementation Impl_f satisfies the specification Spec_f iff:

$$\forall \text{In} \in \text{Dom}. \forall \text{Out} \in \text{CoDom}. (\text{Impl}_f(\text{In}) = \text{Out}) \Rightarrow \text{Spec}_f(\text{In}, \text{Out})$$

Or equivalently:

$$\forall \text{In} \in \text{Dom} \Rightarrow \text{Spec}_f(\text{In}, \text{Impl}_f(\text{In}))$$

- Correctness is always defined with respect to a given specification!

Correctness proof: Induction

Case $\ell_1 = []$: $\ell = [] @ \ell_2 = \ell_2$.

$$\begin{aligned} & (|\ell| = 0 + |\ell_2|) \wedge \\ & (\forall i. 0 \leq i < 0 \Rightarrow \dots) \wedge \\ & (\forall i. 0 \leq i < |\ell_2| \Rightarrow \ell[0 + i] = \ell_2[i]) \end{aligned}$$

Correctness proof: Induction

Case $\ell_1 = a \cdot \ell'_1$: $\ell = a \cdot (\ell'_1 @ \ell_2)$. Let $\ell' = \ell'_1 @ \ell_2$.

- Induction hypothesis:

$$\begin{aligned} & (|\ell'| = |\ell'_1| + |\ell_2|) \wedge \\ & (\forall i \in \text{Nat}. (0 \leq i < |\ell'_1|) \Rightarrow \ell'[i] = \ell'_1[i]) \wedge \\ & (\forall i \in \text{Nat}. (0 \leq i < |\ell_2|) \Rightarrow \ell'[|\ell'_1| + i] = \ell_2[i]) \end{aligned}$$

- 1st point: $|\ell| = 1 + |\ell'_1 @ \ell_2| = 1 + |\ell'_1| + |\ell_2| = |\ell_1| + |\ell_2|$
- We have (by definition of the At operator):
 - ① $\ell[0] = a = \ell_1[0]$,
 - ② $\forall i. 1 \leq i < |\ell_1| \Rightarrow \ell_1[i] = \ell'_1[i - 1]$
 - ③ $\forall i. 1 \leq i < |\ell| \Rightarrow \ell[i] = \ell'[i - 1]$
- 2nd point:
 - | IH.2 $\Rightarrow \forall i. (1 \leq i < |\ell'_1| + 1) \Rightarrow \ell'[i - 1] = \ell'_1[i - 1]$
 - | (2) $\Rightarrow \forall i. (1 \leq i < |\ell_1|) \Rightarrow \ell[i] = \ell_1[i]$
 - | (1) $\Rightarrow \forall i. (0 \leq i < |\ell_1|) \Rightarrow \ell[i] = \ell_1[i]$
- 3rd point: left as an exercise.

Sorting function: An Implementation

- Reason about the structure of the input list?

$$\begin{aligned} \text{Sort}([]) &= \\ \text{Sort}(a \cdot \ell) &= \end{aligned}$$

- How to sort $a \cdot \ell$ if we can sort ℓ ?

Sorting function: An Implementation

- Reason about the structure of the input list?

$$\begin{aligned} \text{Sort}([]) &= [] \\ \text{Sort}(a \cdot \ell) &= \text{Insert}(a, \text{Sort}(\ell)) \end{aligned}$$

- We need to insert a in the sorted list corresponding to ℓ .
- What is the formal specification of *Insert*?
- Type:

$$\text{Insert} : \star \times \text{List}[\star] \rightarrow \text{List}[\star]$$

- Input-Output relation:

$$\begin{aligned} \text{Spec_Insert}(a, \ell, \ell') &= \\ \text{Ordered}(\ell) &\Rightarrow \text{Ordered}(\ell') \wedge (\text{Ms}(\ell') = \text{Sg}(a) \uplus \text{Ms}(\ell)) \end{aligned}$$

Sorting function: Another Implementation

- Reason about the structure of the output list?

$$\begin{aligned} \text{Sort}([]) &= \\ \text{Sort}(a \cdot \ell) &= \end{aligned}$$

- If the output is of the form $e \cdot \ell'$, what is e ? and how to obtain ℓ' ?

Sorting function: Another Implementation

- Reason about the structure of the output list?

$$\begin{aligned} \text{Sort}([]) &= [] \\ \text{Sort}(a \cdot \ell) &= \text{let } (m, \ell_m) = \text{Extract_min}(a, \ell) \text{ in } m \cdot \text{Sort}(\ell_m) \end{aligned}$$

- Extract the minimal element m of ℓ , and sort the rest of the list ℓ_m .

Sorting function: Another Implementation

- Reason about the structure of the output list?

$$\begin{aligned} \text{Sort}([]) &= [] \\ \text{Sort}(a \cdot \ell) &= \text{let } (m, \ell_m) = \text{Extract_min}(a, \ell) \text{ in } m \cdot \text{Sort}(\ell_m) \end{aligned}$$

- Extract the minimal element m of ℓ , and sort the rest of the list ℓ_m .

- Specification of *Extract_min*:

▮ Type: $\text{Extract_min} : \star \times \text{List}[\star] \rightarrow \star \times \text{List}[\star]$

▮ Input-Output relation:

$$\begin{aligned} \text{Spec_Extract_min}(x, \ell_1, m, \ell_2) &= \\ & \text{Is_in}(m, x \cdot \ell_1) \wedge \\ & \forall a \in \star. \text{Is_in}(a, x \cdot \ell_1) \Rightarrow m \leq a \wedge \\ & \text{Ms}(x \cdot \ell_1) = \text{Sg}(m) \uplus \text{Ms}(\ell_2) \end{aligned}$$

Sorting function: Yet Another Implementation

- Reason again about the structure of the output list?

$$\begin{aligned} \text{Sort}([]) &= \\ \text{Sort}(a \cdot \ell) &= \end{aligned}$$

- Assume that when a is at its place in the output, it has ℓ_{left} and ℓ_{right} to its left and right, respectively. How to compute ℓ_{left} and ℓ_{right} ?

Sorting function: Yet Another Implementation

- Reason again about the structure of the output list?

$$\begin{aligned} \text{Sort}([]) &= [] \\ \text{Sort}(a \cdot \ell) &= \text{let } (\ell_1, \ell_2) = \text{split}(a, \ell) \text{ in } \text{Sort}(\ell_1) @ (a \cdot \text{Sort}(\ell_2)) \end{aligned}$$

- Split ℓ into 2 lists containing the elements smaller and greater than a .

Sorting function: Yet Another Implementation

- Reason again about the structure of the output list?

$$\begin{aligned} \text{Sort}([]) &= [] \\ \text{Sort}(a \cdot \ell) &= \text{let } (\ell_1, \ell_2) = \text{split}(a, \ell) \text{ in } \text{Sort}(\ell_1) @ (a \cdot \text{Sort}(\ell_2)) \end{aligned}$$

- Split ℓ into 2 lists containing the elements smaller and greater than a .
- Specification of *Split*:

- Type: $\text{Split} : \star \times \text{List}[\star] \rightarrow \text{List}[\star] \times \text{List}[\star]$
- Input-Output relation:

$$\begin{aligned} \text{Spec_Split}(a, \ell, \ell_1, \ell_2) &= \\ &Ms(\ell) = Ms(\ell_1) \uplus Ms(\ell_2) \wedge \\ &\forall e \in \star. ((\text{Is_In}(e, \ell_1) \Rightarrow e \leq a) \wedge (\text{Is_In}(e, \ell_2) \Rightarrow a < e)) \end{aligned}$$

Proof

Case $\ell = []$: Trivial.

Case $\ell = a \cdot \ell_1$: We have $\ell' = \text{Ins_Sort}(\ell) = \text{Insert}(a, \text{Ins_Sort}(\ell_1))$.

- Let $\ell'_1 = \text{Ins_Sort}(\ell_1)$.
- Induction hypothesis: $\text{Ordered}(\ell'_1) \wedge Ms(\ell_1) = Ms(\ell'_1)$.
- We assume *Insert* correct w.r.t. its specification:

$$\begin{aligned} \text{Spec_Insert}(a, \ell'_1, \ell') &= \\ &\text{Ordered}(\ell') \Rightarrow (\text{Ordered}(\ell') \wedge (Ms(\ell') = \text{Sg}(a) \uplus Ms(\ell'_1))) \end{aligned}$$

- Since we have $\text{Ordered}(\ell'_1)$ by Ind. Hyp., then the following holds:

$$\text{Ordered}(\ell') \wedge (Ms(\ell') = \text{Sg}(a) \uplus Ms(\ell'_1))$$

- We have $Ms(\ell) = \text{Sg}(a) \uplus Ms(\ell_1) = \text{Sg}(a) \uplus Ms(\ell'_1) = Ms(\ell')$.
- Then, we obtain $\text{Ordered}(\ell') \wedge Ms(\ell) = Ms(\ell')$.

Proving correctness of the Recursive Insertion Sort

- Consider the implementation:

$$\begin{aligned} \text{Ins_Sort}([]) &= [] \\ \text{Ins_Sort}(a \cdot \ell) &= \text{Insert}(a, \text{Ins_Sort}(\ell)) \end{aligned}$$

- Assume that *Insert* is correct w.r.t. its specification:

$$\forall a \in \star. \forall \ell, \ell' \in \text{List}[\star]. \text{Insert}(a, \ell) = \ell' \Rightarrow \text{Spec_Insert}(a, \ell, \ell')$$

where

$$\begin{aligned} \text{Spec_Insert}(a, \ell, \ell') &= \\ &\text{Ordered}(\ell) \Rightarrow (\text{Ordered}(\ell') \wedge (Ms(\ell') = \text{Sg}(a) \uplus Ms(\ell))) \end{aligned}$$

- and prove that:

$$\forall \ell, \ell' \in \text{List}[\star]. (\text{Ins_Sort}(\ell) = \ell') \Rightarrow \text{Spec_Sort}(\ell, \ell')$$

where

$$\begin{aligned} \text{Spec_Sort}(\ell, \ell') &= \\ &\forall i, j \in \text{Nat}. (0 \leq i < j < |\ell'| \Rightarrow \ell'[i] \leq \ell'[j]) \wedge \\ &Ms(\ell) = Ms(\ell') \end{aligned}$$

Recursive Insertion

- Type:

$$\text{Insert} : \star \times \text{List}[\star] \rightarrow \text{List}[\star]$$

- Input-Output specification:

$$\begin{aligned} \text{Spec_Insert}(a, \ell, \ell') &= \\ &\text{Ordered}(\ell) \Rightarrow (\text{Ordered}(\ell') \wedge (Ms(\ell') = \text{Sg}(a) \uplus Ms(\ell))) \end{aligned}$$

- Recursive implementation:

$$\begin{aligned} \text{Insert}(a, []) &= a \cdot [] \\ \text{Insert}(a, b \cdot \ell) &= \text{if } a \leq b \text{ then } a \cdot (b \cdot \ell) \\ &\quad \text{else } b \cdot (\text{Insert}(a, \ell)) \end{aligned}$$

Recursive Insertion: Correctness proof

left as an exercise ...

Correctness of the Quick sort

- Consider the sorting function:

$$\begin{aligned} \text{qsort}([]) &= [] \\ \text{qsort}(a \cdot \ell) &= \text{let } (\ell_1, \ell_2) = \text{split}(a, \ell) \text{ in} \\ &\quad \text{qsort}(\ell_1) @ (a \cdot \text{qsort}(\ell_2)) \end{aligned}$$

- Prove that:

$$\forall \ell, \ell'. (\text{qsort}(\ell) = \ell') \implies \text{Spec_Sort}(\ell, \ell')$$

- We need to assume that the two recursive calls are correct.
- What is the proof principle which allows that ?

Well founded relations

- Let E be a set, and let $\prec \subseteq E \times E$ a binary relation over E .
- The relation \prec is well founded if it has no infinite descending chains, i.e., no sequences of the form

$$e_0 \succ e_1 \succ \dots \succ e_i \succ \dots$$

- (E, \prec) is said to be a well founded set (WFS for short).
- Thm: \prec is well founded iff

$$\forall F \subseteq E. F \neq \emptyset \implies (\exists e \in F. \forall e' \in F. e' \not\prec e)$$

Well founded relations: Examples

- $(\mathbb{N}, <)$ is a WFS.
- $(\mathbb{Z}, <)$ is not a WFS.
- $(\mathbb{R}_{>0}, <)$ is not a WFS.

- Let (E, \prec) be a WFS, and let $\rho : D \rightarrow E$.
- Let $\prec_\rho \subseteq D \times D$ be the relation such that:

$$x \prec_\rho y \iff \rho(x) \prec \rho(y)$$

- Induction rule:

$$\frac{\forall x \in D. (\forall y. y \prec_\rho x \Rightarrow P(y)) \Rightarrow P(x)}{\forall x \in D. P(x)}$$

- Consider the WFS $(\mathbb{N}, <)$ and the function $\rho : List[\star] \rightarrow \mathbb{N}$ such that

$$\forall \ell \in List[\star]. \rho(\ell) = |\ell|$$

- The rest of the proof is left as an exercise ...

Conclusion

- Specifications are abstract definitions of the effect of functions.
- No implementation details are imposed. Several implementations can be provided and proved correct w.r.t. an abstract specification.
- Logic is a natural framework for abstract description of input-output relations
- Abstraction allows modular design:
 - ▮ The user of a function needs only to know its specification. This allows to separate issues.
 - ▮ The implementor must ensure the satisfaction of the specification: He/she must prove that its implementation satisfies the required satisfaction.
 - ▮ It is possible to implement a function and prove its correctness w.r.t. to its specification, assuming that the functions it uses (in external modules) are correct w.r.t. their own specifications.
